Ammonium salts of low molecular weight are soluble in water if the hydrocarbon portion of the amine is small. Because the nitrogen atom of an ammonium salt has a positive charge, ammonium salts are more water-soluble than amines. Drugs containing an amino group are often prepared as ammonium salts to improve their solubility in body fluids.

Ammonium salts are ionic compounds with the formula (R)4N + A -, where R is hydrogen, alkyl or aryl groups and A is an anion. When R is alkyl or aryl then they are referred to as quaternary ammonium salts. The quaternary ammonium cations are permanently charged, independent of the pH of their solution. Most of the ammonium salts are soluble in water and strongly dissociated.

Most simple ammonium salts are very soluble in water. An exception is ammonium hexachloroplatinate, the formation of which was once used as a test for ammonium. The ammonium salts of nitrate and especially perchlorate are highly explosive, in these cases ammonium is the reducing agent. In an unusual process, ammonium ions form an amalgam.

The ammonium salt of 3,5-dinitro-1,2,4-triazole has utility as a chemical explosive. In accordance with the present invention, it may readily be produced by solvent extraction using high-molecular weight, water-insoluble amines followed by amination with anhydrous ammonia gas. The aqueous reaction mixture produced in the synthesis of the parent compound, 3,5-dinitro-1,2,4-triazole, is quite suitable--and indeed is preferred--for use as the feed material in the process of the invention.

An investigation was carried out into novel systems for the vulcanization of Viton A, in the hope that vulcanizates displaying improved properties at high temperature (especially with regard to compression set) would result. The following systems were studied: (1) p-Xylylene dihalides in conjunction with sodium alkoxides; (2) 4,4'-dichloromethyl diphenyl oxide in conjunction with sodium alkoxides; (3) quaternary ammonium compounds; (4) dihydric phenols in conjunction with sodium alkoxides; (5) 4,4'-dihydroxymethyl diphenyl oxide in conjunction with sodium alkoxides; (6) 4,4'-diazidodiphenyl; (7) 4,4'-diphenyl bis (diazonium fluoroborate); (8) Pyromellitic dianhydride (dipotassium salt); (9) Dihydrophenazine. Systems 1 and 3 were investigated in greatest detail. It was found that quaternary ammonium salts, both bifunctional and monofunctional, are effective vulcanizing agents, the former being the more effective. The preferred vulcanizing system is comprised of a mixture of equal parts of calcium oxide and 1,4-phenylene dimethylene bis (triethyl ammonium chloride). This system gives vulcanizates with compression set at high temperatures superior to those given by dicinnamylidene hexamethylene diamine. Other mechanical properties and resistance to ageing at 250C in air are similar for vulcanizates prepared with 1,4-phenylene dimethylene bis(triethyl ammonium chloride) and with dicinnamylidene hexamethylene diamine.
